

Project Scope and Non-Scope

Project Scope→

This project focuses on designing and implementing a simple, deterministic reputation system using an Ethereum smart contract.

- Maintain a **reputation** score for each user.
- Apply **time**-based decay to reflect user inactivity.
- Update reputation through defined interaction **rules**.
- Give structured, human-readable **explanations** for every reputation change.
- Allow users to view reputation scores and explanation logs through a minimal frontend user interface.
- Be deployed on an Ethereum test network for demonstration.

Assumptions→

- Each user is represented by a unique blockchain address.
- Users interact directly with the smart contract.
- Time is measured using the blockchain timestamp.
- Reputation values are restricted within a fixed range.
- “THIS IS A SYSTEM NOT A FINAL PRODUCT”
(as this can be added to any pre-existing product for betterment of trust and privacy among the users)

Non-Goals (Out of Scope) →

- Identity verification of users.
- Prevention of Sybil attacks.
- Economic incentives or token-based rewards.
- AI or machine learning-based reputation models.
- Cross-platform reputation aggregation.
- Scalability optimization for large-scale production systems.
- Immediate Real-world commercial deployment.
